

Memo: Golden Pocket – Acquisition Journey Enhancement

TL;DR

This report documents the data analysis and product enhancement initiative aimed at improving the first-time funded rate of Golden Pocket, a CASA (Current Account Savings Account) product built on the MoMo platform. Starting from a stagnant acquisition funnel, the author broke down the drop-off points into three distinct user segments – and validated the root cause of each segment through user interviews and behavioral data analysis. New designs were proposed and tested via a series A/B tests. The result showed that the new home screen drove a statistically significant uplift in the first-time funded rate, while the new registration screen alone did not produce a significant effect.

Disclaimer

This document is intended for knowledge-sharing purposes and demonstrating the author's product thinking, analytical approach, and UX decision-making skills. All specific figures, metrics, and data points presented herein have been altered from their original values to protect confidentiality. While the numbers are not representative of actual performance, the trends, directional insights, and improvements described throughout this report accurately reflect the real outcomes of the project.

1. Background

a. About the product

As aforementioned, Golden Pocket (a.k.a Túi Thần Tài) is a CASA product built within the MoMo app, allowing users to earn daily interest on their deposited balance. Getting started involves three steps: (1) Register by completing a short personal information form, (2) Deposit funds from MoMo wallet or a linked bank account, and (3) Earn interest – after a 2-business-day waiting period, interest accrues and is credited daily. The deposited balance, including both principal and accumulated interest, remains fully liquid at all times and can be used for payments or withdrawn within the MoMo ecosystem whenever needed.

b. Problem statement

After several years of growth and development, the product has accumulated a substantial user base in terms of both registered and monthly funded users (who receive interest payment at least once a month). However, acquisition performance – measured by the **first-time funded rate** (number of users receiving interest for the first time divided by number of visitors to the registration screen within the same timeframe) – has been slowing down and remains stagnant at a relatively low level each month (Figure 1.). This pattern prompted us to rethink how we onboard users and redesign the UX as a whole if needed. The goal is to make it effortless for users to make decisions (to register, to deposit) within seconds.

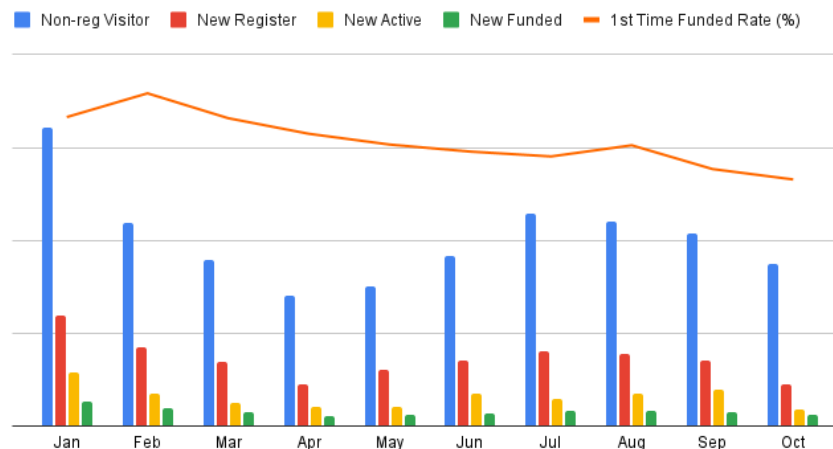

Figure 1. Golden Pocket acquisition funnel by month

c. Segmentation

Looking at the most recent three-month period (Figure 2. below), the overall funnel showed a low conversion rate from visitors to funded users. By breaking down those who did not become funded users, I identified three segments to address:

1. **The unregistered visitors** – Users who visit the Golden Pocket registering screen but choose not to complete the registration process; this group accounts for the largest drop-off point in the funnel.
2. **The inactive registered users** – Users who completed registration but remained inactive throughout the entire month.
3. **The non-funded active users** – Users who made initial transactions and became active, but did not receive any interest amount.

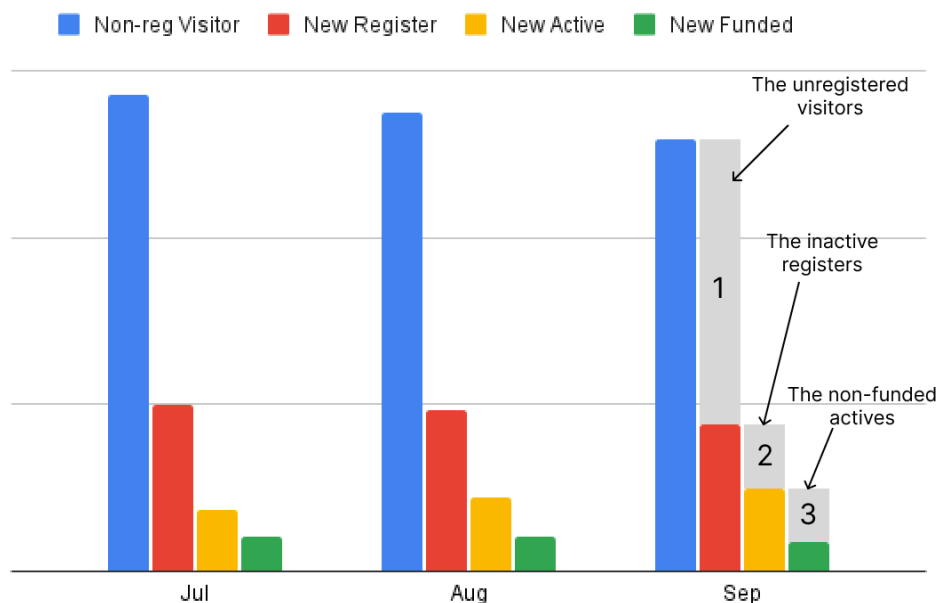

Figure 2. The three target segments

d. Problem verification

i. The unregistered visitors

We conducted user interviews to gather feedback for this group of users. Most users reported not understanding how the product could benefit them when browsing the registration screen, leading them to seek information elsewhere (e.g., searching on Google).

After the initial interviews, we redesigned the screen and ran an A/B experiment. Unfortunately, the new design underperformed compared to the original. This prompted follow-up phone interviews, which revealed a critical insight: users are afraid that registering would entail paying a fee – even if they did not deposit money – because this is a norm for financial products, which caused the hesitation.

ii. The inactive registers

Data analysis of this segment revealed that the majority of the inactive registered users are, in fact, active MoMo users – indicating they trust the MoMo ecosystem. The reluctance to deposit into Golden Pocket appears to stem from confusion about navigating the cluttered home screen, rather than distrust of the product itself. We therefore decided to redesign the post-registration home screen.

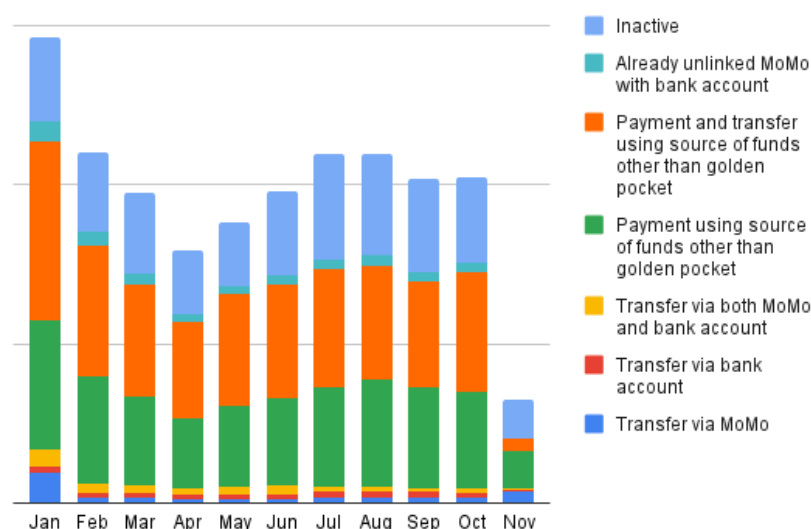

Figure 3. The inactive registered are MoMo active users (within latest 30 days)

iii. The non-funded active users

Analysis showed a notable pattern where a portion of non-funded active users withdrew money back to their MoMo wallet before receiving their first interest payment. This behavior likely stems from unfamiliarity with the interest payment mechanism, which differs from traditional commercial bank operations.

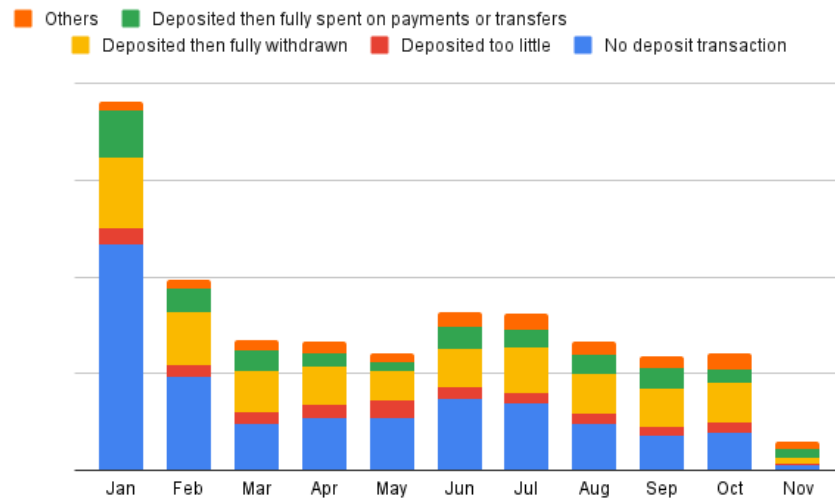

Figure 4. The non-funded active users breakdown

2. The hypothesis

Based on the problems stated in the previous section, with the new designs, we expect users to spend less time and effort understanding what Golden Pocket can do for them and what steps to take next. Specifically:

1. **Unregistered visitors:** should be able to quickly answer: What benefit does the product offer? Is it safe? Are there any fees?
2. **Inactive registered users:** should receive clear, step-by-step guidance immediately after registration so the next action (depositing money) is obvious.
3. **Non-funded active users:** should clearly understand the interest payment mechanism and when to expect their first payment.

3. Solution Space

a. Solution Analysis

For non-registered visitors, we redesigned the registration screen to include Golden Pocket's selling points, a basic explanation of the product mechanism, and partner logos to reinforce trust and safety.

Based on follow-up interview findings, we also added messaging to clarify that no fees are charged – even without depositing – and incorporated this into both the inform-card and call-to-action button.

Image 1. Register screen new designs

For the home screen, we introduced a step-by-step guidance using a progress bar to help users navigate and understand what to do next immediately after registration.

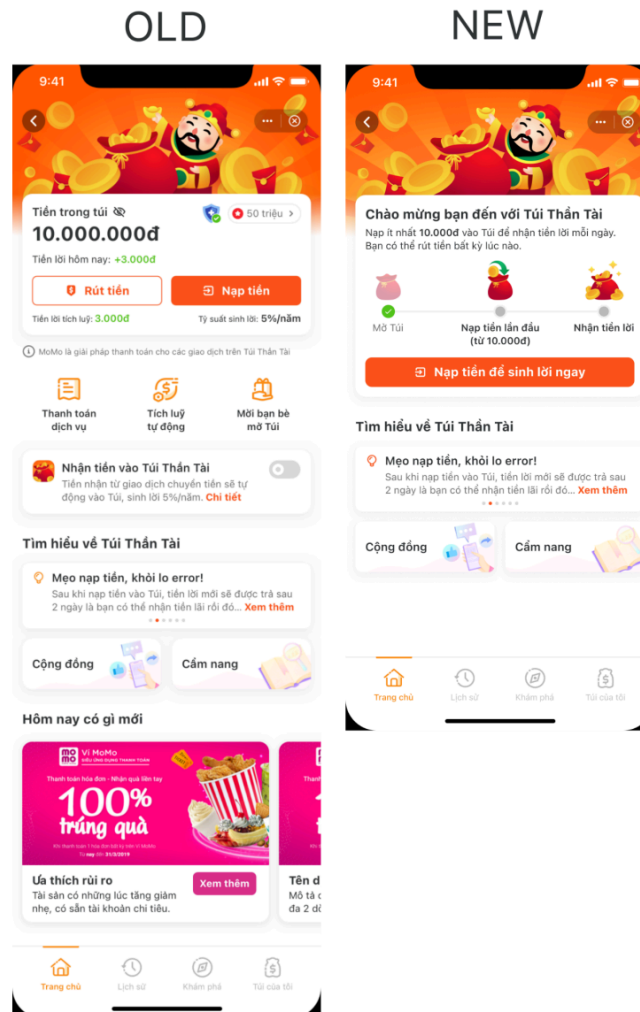

Image 2. Home screen (after registration) new design

b. Implementation tactic

To validate the impact of new solutions, we conducted a series of A/B tests, each testing a new design against its previous version.

4. Launching & Monitoring Update

A/B test results showed that the new home screen with step-by-step guidance significantly outperformed the control group in terms of first-time funded rate, while the new registration screen showed only marginal improvement over the old one. Based on these results, we released the **new home screen combined with the original registration screen** to all users.

Group	Register screen	Home screen	1st time funded rate (%)	Register rate (%)	Statistical significance (z-test)
Control	old	old	6.39	24.91	n/a
Treatment_1	old	new	10.39	25.52	✓ YES
Treatment_2	new	old	7.13	24.9	✗ NO
Treatment_3	new	new	9.75	24.67	✓ YES

Following the launch, the first-time funded rate showed a strongly positive upward trend in the subsequent two months compared to the pre-launch baseline – a meaningful and consistent improvement.

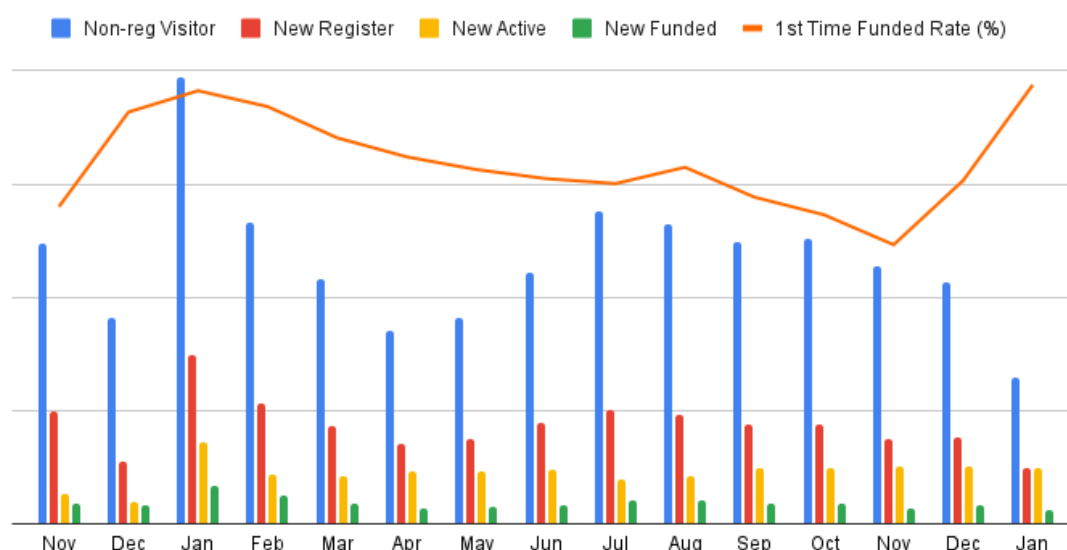

Figure 5. Golden Pocket acquisition performance after deploying new solution to mass users

In spite of the positive results, the percentage of users who can experience the new home screen right after they complete their registration process remains below 100% (reached 68% on 15/01/2024). This is due to some

technical constraints on the front-end, until now, users can only overcome this problem by closing and reopening the MoMo app a few times. The chart below shows the 1st time funded rate (the calculation for this chart is a bit different from traditional 1st time funded rate, which is number of 1st time funded users/number of users complete registration process), we can clearly see that the new home screen still predominates in this setting.

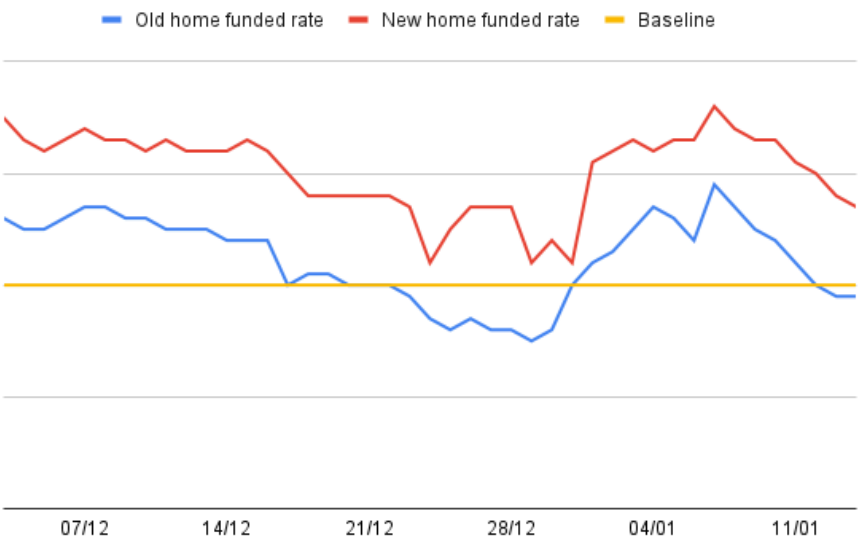

Figure 6. Golden Pocket acquisition performance compared between old screen and new screen
